New understandings about the cause of cavities

Science shows that a bacterial infection causes tooth decay and leads to cavity development. Your dental professional may recommend treating this infection in the absence of, *or* along with any needed dental work.

Additional new findings

Good oral hygiene may not stop cavities.

Even if you brush, floss, and visit your dentist regularly, harmful levels of the decay-causing bacteria may still be present.

A bacterial infection on your teeth can also be transmitted to others. Studies show that harmful decay-causing bacteria can be transmitted to other members of your household.

If the bacterial infection remains untreated, progressive steps of decay may result. Outcomes may include crowns, root canals and ultimately tooth loss.
